```

1. Bioassay model

variance <- var(vector)</pre>

A)

I construct a vector of means with the dimensions 2×1 , and a variance-covariance matrix with the dimensions 2×2 .

```
mean <-c(0, 10)
mean <- matrix(mean, nrow = 2)</pre>
sigma \leftarrow c(2, .6, .6, 10)
sigma <- matrix(sigma, nrow = 2, ncol = 2)</pre>
print(mean)
         [,1]
## [1,]
## [2,]
print(sigma)
        [,1] [,2]
## [1,] 2.0 0.6
## [2,] 0.6 10.0
B)
data("bioassay_posterior")
# Function to calculate expected value with MCSE
# Also adjusts for leading zeros after the decimal
mcse.estimate <- function(vector) {</pre>
  S <- length(vector)</pre>
  estimate <- (1/S)*sum(vector)</pre>
```

```
mcse <- sqrt(variance/S)</pre>
  nu.leadingZeros <- attr(regexpr("(?<=\\.)0+", mcse, perl = TRUE), "match.length")</pre>
  estimate <- round(estimate, nu.leadingZeros)</pre>
  list <- list("Estimate" = estimate,</pre>
                "MCSE"
                         = mcse)
  return(list)
}
# Function to calculate quantile value with MCSE
# Also adjusts for leading zeros after the decimal
mcse.estimateQuantile <- function(vector, prob) {</pre>
  q <- quantile(vector, prob = prob)</pre>
  mcse <- mcse_quantile(vector, prob = prob)</pre>
  nu.leadingZeros <- attr(regexpr("(?<=\\.)0+", mcse, perl = TRUE), "match.length")</pre>
  q <- round(q, nu.leadingZeros)</pre>
  list <- list("Quantile" = q,</pre>
                "MCSE" = mcse)
  return(list)
Below I describe the values for \alpha:
# Values for alpha
alpha <- bioassay_posterior$alpha
mcseEstimate <- mcse.estimate(alpha)</pre>
mcse.estimateQuantile05 <- mcse.estimateQuantile(alpha, prob = 0.05)</pre>
mcse.estimateQuantile95 <- mcse.estimateQuantile(alpha, prob = 0.95)</pre>
print(mcseEstimate)
## $Estimate

## 95%
##
  20
##
## $MCSE
##
          mcse
## 1 0.2412129
```

Importance sampling:

C)

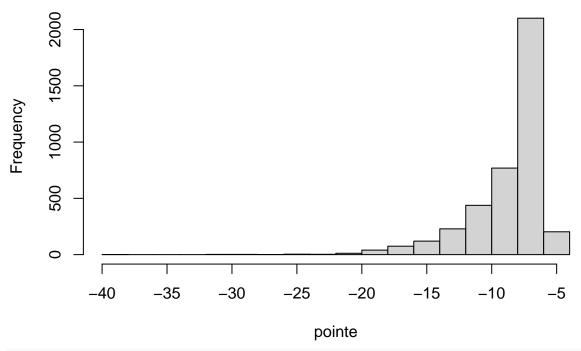

Notice here that $w(\theta^s) = \frac{q(\theta^s|y)}{g(\theta)} = q(y|\theta^s)$ when we assumed that the prior distribution $p(\theta)$ equals our proposal distribution $g(\theta)$. Thus, our function is given below. Also, we work with logs because it makes things computationally easier!

```
library(aaltobda)
data("bioassay")
bioassay
```

```
## x n y
## 1 -0.86 5 0
```

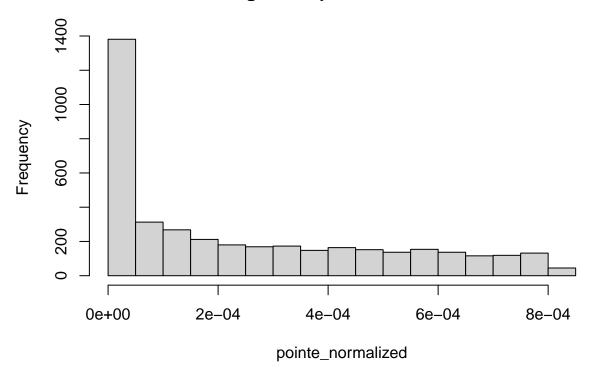

```
## 2 -0.30 5 1
## 3 -0.05 5 3
## 4 0.73 5 5
alpha \leftarrow c(1.896, -3.6, 0.374, 0.964, -3.123, -1.581)
beta <- c(24.76, 20.04, 6.15, 18.65, 8.16, 17.4)
log_importance_weights <- function(alpha, beta) {</pre>
  log.like <- bioassaylp(alpha, beta, bioassay$x, bioassay$y, bioassay$n)</pre>
  return(log.like)
}
pointc <- log_importance_weights(alpha, beta)</pre>
round(pointc,2)
## [1] -8.95 -23.47 -6.02 -8.13 -16.61 -14.57
D)
The effect of exponentiation and scaling makes things easier for interpretation.
normalized_importance_weights <- function(alpha, beta) {</pre>
  log.like <- bioassaylp(alpha, beta, bioassay$x, bioassay$y, bioassay$n)</pre>
  like <- exp(log.like)</pre>
  denominator <- sum(like)</pre>
  return(like/denominator)
}
pointd <- normalized_importance_weights(alpha = alpha, beta = beta)</pre>
round(pointd, 3)
## [1] 0.045 0.000 0.852 0.103 0.000 0.000
\mathbf{E})
sims <- 4000
theta <- rmvnorm(sims, mean = mean, sigma = sigma)
alphaE <- theta[,1]</pre>
betaE <- theta[,2]</pre>
pointe <- log_importance_weights(alpha = alphaE, beta = betaE)</pre>
pointe_normalized <- normalized_importance_weights(alpha = alphaE, beta = betaE)
hist(pointe)
```

Histogram of pointe

hist(pointe_normalized)

Histogram of pointe_normalized

F)Below I show the sampling effective sample size.

```
S_eff <- function(alpha, beta) {
    Seff <- 1/sum(normalized_importance_weights(alpha, beta)^2)
    return(Seff)
}
Seff <- S_eff(theta[,1], theta[,2])
print(Seff)
## [1] 1979.788</pre>
```

G)

To analyze the possibility of missing some extremely large importance weights, we can look at the sampling effective sample size. If small, it indicates that there are only a handful of extremely high weights. If big, then it shows that it has many extremely high weights.

H)

Denote E(.) the function to get the expected value of a function in terms of importance weights. The function of interest is $h(\theta^s) = \theta^s$. Thus, $E(\theta)$.

```
posterior_mean <- function(alpha, beta) {</pre>
  theta <- list(alpha, beta)
  lst <- list()</pre>
  i <- 0
  log.like <- bioassaylp(alpha, beta, bioassay$x, bioassay$y, bioassay$n)</pre>
  like <- exp(log.like)</pre>
  for(t in theta) {
    i <- 1 + i
    estimate <- mean(t*like)/mean(like)</pre>
    mcse <- (mean(t*like^2)/mean(like^2)) - estimate^2</pre>
    nu.leadingZeros <- attr(regexpr("(?<=\\.)0+", mcse, perl = TRUE), "match.length")</pre>
    estimate <- round(estimate, nu.leadingZeros)</pre>
    lst[i] <- estimate</pre>
    i <- 1 + i
    lst[i] <- mcse[1]</pre>
  }
  return(lst)
}
pstmean <- posterior_mean(theta[,1], theta[,2])</pre>
print(pstmean)
```
